Abstract—This paper presents system analysis, modeling and simulation of an Electric Vehicle (EV) with three different control strategies: Field Oriented Control (FOC), Direct Torque Control (DTC), and DTC using Space Vector Modulation (DTC-SVM). The objective is to assess the control strategy impact on the EV efficiency taking into account the vehicle dynamics. Indeed, among EV motor electric propulsion features, the energy efficiency is a basic characteristic that is influenced by vehicle dynamics and system architecture. Simulation tests have been carried out on a 37-kW EV that consists in an induction motor with a three-level IGBT inverter. Preliminary results seem to indicate that the DTC-SVM scheme is the best candidate.

Keywords—Electric vehicle, induction motor, efficiency, field oriented control, Direct torque control, space vector modulation.

I. INTRODUCTION

Electric vehicles are set to improve the energy and environmental impact of an increasing road transport population by offering a more energy efficient and less polluting drive-train alternative to conventional internal combustion engine vehicles. So the electric vehicle production is expected to increase dramatically these years. The electric propulsion system is the heart of EV [1]. It consists of the motor drive, transmission device, and wheels. In fact, the motor drive, comprising of the electric motor, power converter, and electronic controller, is the core of the EV propulsion system. The motor drive is configured to respond to a torque demand set by the driver. Many researches [2-3] have demonstrated the induction motor is one of the right electric motor candidates for the most EVs due to its low cost, robustness, highly reliable and free from maintenance.

However, induction motors constitute a theoretically challenging control problem since the dynamical system is nonlinear, the electric rotor variables are not measurable, and the physical parameters are most often imprecisely known. In addition, unlike the traditional industrial setting, in which the induction motor operates mostly at steady state, the EV applications require high performance control of electric

motors to obtain fast transient responses and energy efficiency. Important characteristics of an EV motor include good drive control and fault tolerance, as well as low noise with high efficiency. The control of the induction motor for EVs has attracted much attention in the past five years; especially the speed sensorless control of induction motors has been a popular area due to its low cost and strong robustness [3].

In recent years, FOC induction motor drives have greatly increased. In parallel, a number of studies have been developed to find out different solutions for the control of the induction motor drives with two objectives, namely achievement of a precise and quick control of the field motor and torque like in FOC drives, and reduction of the complexity of the algorithms involved in a FOC control.

Among the various proposals, DTC is an entirely different approach to induction motor torque control that was developed to overcome FOC relatively poor transient response and reliance on induction motor parameters. However, beside some attractive features such as fast dynamic response, low sensitivity to parameter changes, lack of internal current control loops and inherently motion sensorless operation [4-5] there exist some problems associated with DTC, namely: difficult to start and low-speed operation, high current and torque ripple, variable switching frequency and high noise level, violence of polarity consistency rules (to avoid ± 1 switching over dc-link voltage), as well as high sampling frequency needed for digital implementation of hysteresis controllers. Most of above difficulties can be eliminated when instead of the hysteresis controllers with switching table a linear PI controller with a voltage pulse width modulator (PWM) are used. The PI controllers calculate the required stator voltage vector, averaged over a sampling period. The voltage vector is finally synthesized by a PWM technique, which in most cases is the space vector modulation (SVM). Therefore, contrary to the conventional DTC solution, in a DTC-SVM scheme the switching harmonics are neglected in the control algorithm [6].

This paper presents then three different control methods for EVs propulsion in order to achieve the propulsion optimized efficiency.

II. VEHICLE MODEL

Compared to previous works, the proposed control strategy takes into account the vehicle aerodynamics, and is not applied to the sole induction motors. This model is based on the principles of vehicle mechanics and aerodynamics [7]. The total tractive effort is then given by

$$F_{te} = F_{rr} + F_{ad} + F_{hc} + F_{la} + F_{wa} \quad (1)$$

Where F_{rr} = is the rolling resistance force;
 F_{ad} = is the aerodynamic drag;
 F_{hc} = is the hill climbing force;
 F_{la} = is the force required to give linear acceleration;
 F_{wa} = is the force required to give angular acceleration to the rotating motor.

It should be noted that F_{la} and F_{wa} will be negative if the vehicle is slowing down and that F_{hc} will be negative if it is going downhill. The power required to drive a vehicle at a speed v has to compensate counteracting forces.

$$P_{te} = vF_{te} = v(F_{rr} + F_{ad} + F_{hc} + F_{la} + F_{wa}) \quad (2)$$

The efficiency of the motor and its controller are usually considered together, as it is more convenient to measure the efficiency of the whole system. We saw that motor efficiency varies considerably with power, torque, and also motor size [8]. The efficiency is quite well modeled by

$$\eta_m = \frac{T\omega}{T\omega + k_c T^2 + k_i \omega + k_w \omega^3 + C} \quad (3)$$

Where k_c is the copper losses coefficient, k_i is the iron losses coefficient, k_w is the windage loss coefficient and C represents the constant losses that apply at any speed. Table 1 shows typical values for these constants for two motors that are likely candidates for use in electric vehicles.

Table 1. Typical values for the parameters of (3).

Parameters	Lynch type PM motor, with brushes, 2-5 kW	100 kW, high speed induction motor
k_c	1.5	0.3
k_i	0.1	0.01
k_w	10^{-5}	5.0×10^{-6}
C	20	600

III. CONTROL METHODS

A number of different control schemes for accurate torque control of an induction motor for this electric vehicle application, have been investigated. FOC and DTC were chosen for simulation, as they are standard induction motor control techniques. An improvement to DTC is DTC-SVM, a new torque control scheme that is also simulated.

A. Nomenclature

V_{ds} (V_{qs}) = d -axis (q -axis) stator voltages;
 i_{ds} (i_{qs}) = d -axis (q -axis) stator currents;

λ_{dr} (λ_{qr}) = d -axis (q -axis) rotor flux linkages;
 R_s (R_r) = Stator (rotor) resistance;
 L_s (L_r) = Stator (rotor) inductance;
 L_m = Magnetizing inductance;
 L_σ = Leakage inductance ($L_\sigma = L_s - L_m^2/L_r$);
 ω_e (ω_r) = Stator (rotor) electrical speed;
 Ω = Rotor speed (ω_r/p);
 ω_{sl} = Slip frequency, $\omega_{sl} = \omega_s - \omega_r$
 B = Motor damping ratio;
 p = pole-pair number.

$$\begin{cases} k_1 = \frac{R_s}{L_\sigma} + \frac{R_r L_m^2}{L_r^2 L_\sigma}, k_2 = \frac{R_r L_m}{L_r^2 L_\sigma}, k_3 = \frac{L_m}{L_r L_\sigma}, \\ k_4 = \frac{R_r L_m}{L_r}, k_5 = \frac{R_r}{L_r}, k_6 = \frac{1}{L_\sigma}, k_7 = \frac{3}{2} p \frac{L_m}{L_r} \end{cases}$$

B. FOC

Generally, dynamic modeling of an induction motor drive is based on rotating reference-frame theory and a linear technique. A system configuration of an induction motor drive is shown in Fig. 1. This motor drive consists of an induction motor, a bang-bang current-controlled pulse width modulated (PWM) inverter, a field-orientation mechanism, a coordinate translator and a speed controller. The electrical dynamics of an induction motor in the synchronously rotating reference frame (d - q -axis) can be expressed by (4-6) [9-10].

$$\frac{d}{dt} \begin{bmatrix} i_{ds} \\ i_{qs} \\ \lambda_{dr} \\ \lambda_{qr} \end{bmatrix} = \begin{bmatrix} -k_1 & \omega_e & k_2 & \omega_r k_3 \\ -\omega_e & -k_1 & -\omega_r k_3 & k_2 \\ k_4 & 0 & -k_5 & \omega_{sl} \\ 0 & k_4 & -\omega_{sl} & -k_5 \end{bmatrix} \begin{bmatrix} i_{ds} \\ i_{qs} \\ \lambda_{dr} \\ \lambda_{qr} \end{bmatrix} + k_6 \begin{bmatrix} V_{ds} \\ V_{qs} \\ 0 \\ 0 \end{bmatrix} \quad (4)$$

$$\frac{d\omega_r}{dt} = -\frac{B}{J} \omega_r - \frac{1}{J} (T_m - T_L) \quad (5)$$

$$T_m = k_t (\lambda_{dr} i_{qs} - \lambda_{qr} i_{ds}) \quad (6)$$

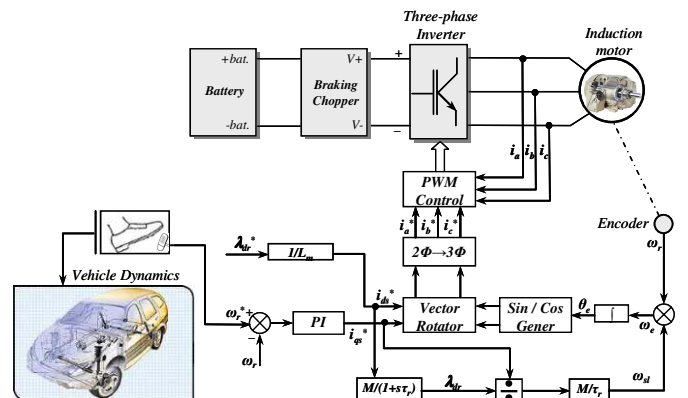

Fig. 1. Direct field-oriented induction motor drive.

C. DTC

The basic idea of the method is to calculate flux and torque instantaneous values only from the stator variables. Flux, torque, and speed are estimated. The input of the motor controller is the reference speed, which is directly applied by the pedal of the vehicle. Control is carried out by hysteresis comparators and a switching logic table selecting the appropriate voltage inverter switching configurations [7], [11]. Figure 2 gives the global configuration of a DTC scheme and also shows how the EV dynamics will be taken into account. The induction motor mechanical equation is as follows.

$$J \frac{d\omega_r}{dt} + T_B + T_L = T_m \quad (7)$$

The induction motor stator flux can be estimated by

$$\begin{cases} \lambda_{ds} = \int (V_{ds} - R_s i_{ds}) dt \\ \lambda_{qs} = \int (V_{qs} - R_s i_{qs}) dt \\ |\lambda_s| = \sqrt{\lambda_{ds}^2 + \lambda_{qs}^2} \\ \theta_{\lambda_s} = \tan^{-1} \left(\frac{\lambda_{qs}}{\lambda_{ds}} \right) \end{cases} \quad (8)$$

Then, the electromagnetic torque is estimated using

$$T_m = \frac{3}{2} \frac{p}{2} (\lambda_{ds} i_{qs} - \lambda_{qs} i_{ds}) \quad (9)$$

D. DTC-SVM

With the development of microprocessors and DSP techniques, the SVM technique has become one of the most important PWM methods for Voltage Source Inverter (VSI) since it gives a large linear control range, less harmonic distortion, fast transient response, and simple digital implementation [12-13].

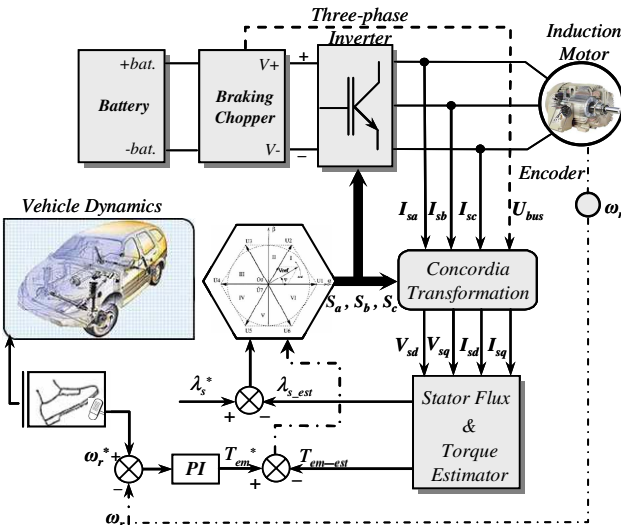

Fig. 2. DTC block diagram.

The SVM principle is based on the switching between two adjacent active vectors and two zero vectors during one switching period. It uses the space vector concept to compute the duty cycle of the switches. Fig. 3 shows a scheme of a three-phase two-level inverter with a star-connection load.

From Fig.3, the output voltages of the inverter can be composed by eight states $u_0, u_1 \dots u_7$, corresponding to the switch states $S_0(000), S_1(100), \dots, S_7(111)$, respectively. These vectors can be plotted on the complex plane (α - β) as shown in Fig.4, and are given by [3]

$$u_k = \begin{cases} \frac{2}{3} V_{dc} e^{j(k-1)(\pi/3)} & \text{for } k=1, 2, \dots, 6 \\ 0 & \text{for } k=0, 7 \end{cases}$$

The rotating voltage vector within the six sectors can be approximated by sampling the vector and switching between different inverter states during the sampling period [13]. The vector u_s is commonly split into two nearest adjacent voltage vectors and zero u_0 and u_7 in an arbitrary sector. For example, during one sampling interval, vector u_s in sector I can be expressed as

$$u_s(t) = \frac{T_0}{T_s} u_0 + \frac{T_1}{T_s} u_1 + \frac{T_2}{T_s} u_2 + \frac{T_7}{T_s} u_7 \quad (10)$$

Where T_0, T_1, T_2, T_7 are the turn-on time of the vectors u_0, u_1, u_2, u_7 ; and T_s is the sampling time. $T_s - T_1 - T_2 = T_0 + T_7 \geq 0$, $T_0 \geq 0$ and $T_7 \geq 0$.

Fig. 3. Three-phase two-level inverter.

Fig. 4. Space vectors.

The block diagram of the DTC-SVM control scheme for voltage source inverter-fed IM is shown in Fig. 5 [14]. In this method two PI controllers are used for torque and flux regulation. The outputs of the PI flux and torque controllers generate the reference stator voltage components U_{sd} , U_{sq} expressed in the stator flux oriented coordinates ($d-q$). These components are dc voltage commands and then transformed into stationary coordinates ($\alpha-\beta$) the commanded values $U_{s\alpha}$, $U_{s\beta}$ are delivered to space vector modulator (SVM), which generates switching signals S_a , S_b , S_c for power transistors. [3-6]

V. SIMULATION RESULTS

Numerical simulations have been carried out, on an EV propelled by 37-kW induction motor drives. The objectives of the carried out simulations are to assess the efficiency and dynamic performances of the different control strategies. The test cycle is the urban ECE-15 + sub-urban cycle (Fig. 6).

Regarding the obtained results shown by Figs 7 to 8, DTC techniques exhibit improved transient torque response compared to standard rotor flux FOC. The disadvantage of the compared schemes is increased current distortion, resulting in increased motor losses. DTC-SVM is an exception that exhibit low current distortion and also fast torque response and low torque ripple. Therefore, these results seem to indicate that the DTC-SVM scheme is the best candidate for an EV drive optimized control.

Fig. 5. DTC-SVM block diagram.

Fig. 6. (ECE-15 + sub-urban) driving cycle.

Figure 9 illustrate the efficiency of the motor and its controller, one can notice that there is not a great difference between the FOC and the DTC, the DTC-SVM technique represent less chattering compared to the two preceding techniques, this advantage confirms well that DTCSVM is a good candidate if one wants to make the optimization of the total energy of the vehicle.

Figure 10 shows the induction motor flux for conventional DTC and DTC-SVM controller, in the beginning of the simulation process, the nominal flux is applied to the induction motor drive until it reaches its steady state. One can confirm that the system is stable for the two control techniques, with elimination of the chattering for DTC-SVM.

VI. CONCLUSION

This paper dealt with the comparative analysis of three control schemes for electric vehicles efficiency improvement; namely: FOC, DTC, and DTC-SVM. These control schemes were simulated using an induction motor model combined the vehicle aerodynamics. The DTC-SVM control can achieve the complete decoupled control of torque and flux and significant torque ripple reduction. Compared with the conventional DTC and FOC control methods, it has low torque ripple, low current distortion and high-performance dynamic characteristics. The limited power supply in EV requires a high efficiency electrical drive system. The drive for such a system must have a quick response and simple configuration. A suitable control strategy having the above mentioned features for the electrical drive is the DTC-SVM technique.

APPENDIX

RATED DATA OF THE SIMULATED INDUCTION MOTOR

37 kW, 50 Hz, 400/230 V, 64/111 A, 24.17 Nm, 2960 rpm
$R_s = 85.1 \text{ m}\Omega$, $R_r = 65.8 \text{ m}\Omega$
$L_s = 31.4 \text{ mH}$, $L_r = 29.1 \text{ mH}$, $L_m = 29.1 \text{ mH}$
$J = 0.23 \text{ kg.m}^2$

EV MECHANICAL AND AERODYNAMIC PARAMETERS

$m = 1540 \text{ kg}$ (two 70 kg passengers), $A = 1.8 \text{ m}^2$, $r = 0.3 \text{ m}$
$\mu_{rr1} = 0.0055$, $\mu_{rr2} = 0.056$, $C_{ad} = 0.19$, $G = 104$, $\eta_g = 0.95$
$T = 57.2 \text{ Nm}$ (stall torque), $v_0 = 4.155 \text{ m/sec}$
$g = 9.81 \text{ m/sec}^2$, $\rho = 0.23 \text{ kg/m}^3$

Abdelhakim Haddoun was born in Constantine, Algeria, in 1967. He received the B.Sc. and the M.Sc. degrees in Electrical Engineering, from the University of Batna, Algeria, in 1993 and 1999 respectively. In 2000, he joined the Electrical Engineering Department of the University of Oum El Bouaghi, Algeria, as a Teaching Assistant.

He is currently pursuing Ph.D. studies on electric vehicle control and power management.

Mohamed El Hachemi Benbouzid (S'92-M'95-SM'98) was born in Batna, Algeria, in 1968. He received the B.Sc. degree in electrical engineering from the University of Batna, Batna, Algeria, in 1990, the M.Sc. and Ph.D. degrees in electrical and computer engineering from the National Polytechnic Institute of Grenoble, Grenoble, France, in 1991 and 1994, respectively, and the Habilitation à Diriger des Recherches degree from the University of Picardie "Jules Verne," Amiens, France, in 2000.

After receiving the Ph.D. degree, he joined the Professional Institute of Amiens, University of Picardie "Jules Verne," where he was an Associate Professor of electrical and computer engineering. In September 2004, he joined the University Institute of Technology (IUT) of Brest, University of Western Brittany, Brest, France, as a Professor of electrical engineering. His main research interests and experience include analysis, design, and control of electric machines, variable-speed drives for traction and propulsion applications, and fault diagnosis of electric machines.

Prof. Benbouzid is a Senior Member of the IEEE Power Engineering, Industrial Electronics, Industry Applications, Power Electronics, and Vehicular Technology Societies. He is an Associate Editor of the IEEE TRANSACTIONS ON ENERGY CONVERSION, the IEEE TRANSACTIONS ON INDUSTRIAL ELECTRONICS, the IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY, and the IEEE/ASME TRANSACTIONS ON MECHATRONICS.

Demba Diallo (M'99-SM'05) was born in Dakar, Senegal, in 1966. He received the M.Sc. and Ph.D. degrees both in Electrical and Computer Engineering, from the National Polytechnic Institute of Grenoble, France, in 1990 and 1993 respectively.

From 1994 to 1999, he worked as a Research Engineer in the Laboratoire d'Electrotechnique de Grenoble, France, on electrical drives and active filters (hardware and software). In 1999 he joined the University of Picardie "Jules Verne" as Associate Professor of Electrical engineering. In September 2004, he joins the IUT of Cachan, University of Paris Sud P11 as an Associate Professor of Electrical Engineering. He is with the Laboratoire de Génie Electrique de Paris. In December 2005, he received the "Habilitation à Diriger des Recherches" degree from the University of Paris Sud P11. His current area of research includes advanced control techniques and diagnosis in the field of ac drives.

D. Diallo is a Senior Member of the IEEE Industry Applications, Vehicular Technology and Control Systems Societies.

Rachid Abdessemed was born in Batna, Algeria, in 1951. He received the M.Sc. and Ph.D. degrees in Electrical Engineering, from Kiev Polytechnic Institute, Ukraine, in 1978 and 1982 respectively.

He has been working for more than eighteen years at the University of Batna where he is a Professor in the Electrical Engineering Department. Currently, he is the Director of the Electrical Engineering Laboratory. His current area of research includes design and control of induction machines, reliability, magnetic bearings, and renewable energy.

Jamel Ghouili was born in Ghardimaou, Tunisia, in 1962. He is currently Professor at the University of Moncton, Canada, where he is responsible of the power electronics and drives Teaching and Research program since 2000. He received the B.Sc., the M.Sc. and the Ph.D. degrees from University of Québec at Trois-Rivières, Canada, in 1986, 1998 and 2004 respectively. Early in his career, he served as Professor at Ecole Polytechnique de Masuku, Gabon. His main research interests include power converters, ac drives, DSP and FPGA control,

sensorless control, EV/HEV drives, fuzzy logic and neural network applications in power electronics and drives.

Kamel Srairi was born in Batna, Algeria, in 1967. He received the B.Sc. degree in Electrical Engineering, in 1991, from the University of Batna, Algeria; the M.Sc. degree in Electrical and Computer Engineering, from the National Polytechnic Institute of Grenoble, France, in 1992; and the Ph.D. degree also in Electrical and Computer Engineering, from the University of Nantes, France, in 1996.

After graduation, he joined the University of Biskra, Algeria, where he is a Professor in the Electrical Engineering Department. His main research interests include analysis, design, and control of electric machines.
